Abstract

Background: The purpose of this study was to describe the association of MTHFR gene single nucleotide polymorphisms (C677T and A1298C) and maternal supplementary folate intake with orofacial clefts in the Iranian population.

Methods: In this case-control study, peripheral venous blood was taken from 65 patients with orofacial clefts and 215 unaffected controls for DNA extraction and kept in EDTA for further analysis. The genotyping was carried out using Polymerase Chain Reaction (PCR) followed by Restriction Fragment Length Polymorphism (RFLP) and gel electrophoresis. Data were analyzed using Chi square test and logistic regression tests.

Results: Genotype frequencies of 677TT were reported to be 13.5 and 36.1% in controls and CL/P patients, respectively, which showed a significant difference compared to CC as reference (OR=4.118; 95% CI=1.997-8.492; p=0.001). Conversely, 1298CC with frequencies of 10.8 and 12.7% in controls and patients, respectively, showed no significant difference compared to AA (OR=2.359; 95% CI=0.792-7.023; p=0.123). Comparing patients whose mothers did not report the folate supplement intake during pregnancy, to controls, it was observed that lack of folate intake was a predisposing factor for having a child with oral clefts (OR=5/718, p=0.000).

Conclusion: Children carrying the 677TT variant of the MTHFR gene may have an increased risk of CL/P. In addition, the finding that the risk associated with this allele was obviously higher when the mothers didn’t use folic acid, supports the hypothesis that folic acid may play a role in the etiology of CL/P.

Keywords: Cleft lip, Cleft palate, Genes, Polymorphism

Introduction

Cleft lip with or without cleft palate (CL/P) is among the most common orofacial congenital anomalies in the world 1. Several epidemiological studies have reported the prevalence of cleft lip and/or palate in Iran and worldwide 2-8. Nonsyndromic CL/P (nsCL/P) follows a multifactorial inheritance pattern in which both environmental and genetic factors are considered to play a significant role 8.

Determining the genetic risk factors of CL/P has been the subject of numerous studies 10. Also, it has been claimed that environmental factors such as maternal folic acid intake affect the risk of orofacial clefts in some pregnancies, thus, it might be hypothesized that variants of genes involved in folic acid metabolism pathway, could be associated with the risk 9,11. Among genes taking part in folate metabolism, the methylene tetrahydrofolate reductase gene (MTHFR) has been the most frequent one which is associated with nsCL/P 12-14.

It produces an enzyme which catalyzes the methylation of homocysteine amino acid to methionine. Any defect on this pathway can result in methionine deficiency and the accumulation of homocysteine. In addition to critical role of methionine as an important pre-
cursor in the DNA and RNA methylation process, high serum homocysteine levels are teratogenic during the embryogenesis\textsuperscript{15,16}.

Within the \textit{MTHFR} gene, two common polymorphisms, (C---T) and (A---C), exist at positions 677 and 1298, respectively.\textsuperscript{17} Several associations have been reported between the polymorphisms in the \textit{MTHFR} gene and the risk of nsCL/P\textsuperscript{12-14}. However, results have been contradictory as in a study conducted by Han \textit{et al}. It was shown that A1298C polymorphism would have a protective role rather than being a predisposing factor for cleft lip and palate\textsuperscript{18}.

Numerous studies evaluated the relationship between MTHFR gene polymorphisms and nsCL/P but none of them examined Iranian patients. As a comprehensive genetic study on CL/P, a case-control study of the \textit{MTHFR} polymorphisms was performed. The main objective of the present study was to determine the association between nsCL/P and C677T, A1298C polymorphisms in the \textit{MTHFR} gene and the role of maternal supplementary folate intake as a risk factor for nonsyndromic orofacial clefts.

**Materials and Methods**

In this study, 65 patients with nonsyndromic CL/P (isolated CL/P without any other organ disorders) and 215 unaffected controls were included which were matched to cases regarding age, gender and socioeconomic status. Patients with other facial or skeletal malformations, metabolic or neurologic disorders or anomalies of other organ systems were excluded. Samples were recruited from Mofid Hospital in Tehran, Iran in 2012-2013. Ethical approval for the study was obtained from the Ethics Committee of the Dental Research Center in Shahid Beheshti University for dento-facial deformities. Informed consent was obtained from all parents.

Questions on family members were intended to find other affected family members or possible minimal variants of orofacial clefts among relatives. In order to identify any possible prenatal contributory teratogenic factor that might have influenced the development of CL/P, a detailed questionnaire was applied. The questionnaire was modeled on the Centers for Disease Control (CDC) questionnaire for risk factor surveillance for birth defects (www.cdc.gov/surveillance/eppractice/a_z.html). All mothers were questioned for maternal illnesses, medication intake, history of abortion, history of cardiovascular diseases, and smoking. In this way, confounding factors associated with orofacial clefts could be limited. Control children whose mothers reported positive history of mentioned factors were excluded. In addition, the history of folate intake during the periconceptional period (ranging from 3 months prior to 1 month after conception) was evaluated through questionnaire among mothers of cases.

Peripheral venous blood was taken for DNA extraction from all affected individuals and controls.

**Genotype analysis**

Blood samples were collected in tubes containing 200 \textit{\mu}l of 0.5 \textit{M} EDTA and stored at -80°C until further analysis. Genotyping for C677T and A1298C gene mutations were performed by enzymatic restriction digestion of PCR products with HinfI and MboII enzymes, respectively\textsuperscript{19,20}.

For screening the 677C---T and 1298A---C variants in the \textit{MTHFR} gene, exons 4 and 7 of the gene were amplified by Polymerase Chain Reaction (PCR) following standard conditions and with the use of modified primers (4F: 5'-TCTTCATCCCTCGCCCTGTGA 3'; 4R: 5'-AGGACCGTGCGGTGAGAATG-3') and (7F: 5'-CTTCTACCTGAAAGCAAGTC-3' 7R: 5'-CATGTCACAGCATGAGA-3'), respectively. DNA fragments were separated and visualized by electrophoresis using 8% polyacrylamide gels (Figures 1 and 2).

**Statistical methods**

Statistical analyses were performed using SPSS 11.5 software and data were shown as the allele frequencies and percentages. Chi square test was used to determine the difference in the genotype and gene frequency. Odds Ratios (OR) with 95% Confidence Interval (CI) were calculated from logistic regression models. P<0.05 was considered to indicate a statistically significant result.

Results

There were three genotypes for each variant (CC, CT and TT for C677T and AA, CC and AC for A1298C), in MTHFR gene in the two groups. Table 1 shows that compared to the CC genotype, the TT genotype was significantly correlated with an increased risk of CL/P (OR=4.1; 95% CI=2.8-5.3; p<0.001) while comparing to the AA genotype, the CC genotype did not show a significant difference (OR=2.4; 95% CI=0.8-7; p=0.123).

According to table 2, the frequencies of the C and T alleles of C677T and A and C alleles of A1298C were 69.7%, 30.3%, 62.9% and 37.1% in the control group, respectively and 49.1%, 50.9%, 63.1% and 36.9% in the CL/P group, respectively.

Moreover, the cases were divided into two separate groups according to maternal folate intake history. Group 1 included CL/P children whose mothers had reported folate supplement intake in the questionnaire (n=23, 37.1% in C677T and n=26, 40% in A1298C) which is shown in table 3, and group 2 included affected children whose mothers did not mention folate supplement intake (n=39, 62.9% in C677T and n=39, 60% in A1298C) (Table 4).

According to table 4, compared to the CC genotype, the TT genotype was significantly correlated with an increased risk of CL/P in group 2 and this correlation was greater than the amount found in Table 1 for all of the patients compared to controls (OR=5.7 vs. OR=4.1), while this correlation was not significant according to A1298C genotypes. This finding supports the preventive effect of folate intake even in those with predisposing genotype.

Discussion

MTHFR is one of the major enzymes in the metabolism of folic acid which catalyzes the irreversible reduction of 5, 10- methylenetetrahydrofolate to 5- methylenetetrahydrofolate \(^{21}\). A change of C to T at nucleotide 677 and A to C at nucleotide 1298 in MTHFR C677T and A1298C, results in an amino acid sequence change of an alanine to valine and glutamine to alanine, respectively. Mutant protein has reduced enzyme activity which leads to DNA hypomethylation and may induce genomic instability, thereby affecting the expression of oncogenes or tumor suppressor genes \(^{22}\).

Several studies have been conducted to determine the association between the two functional polymorphisms (C677T and A1298C) in MTHFR gene and an increased risk of CL/P \(^{23,24}\). However, the results are inconsistent due to differences in the studied populations, various genetic backgrounds and different exposures to diverse environmental risk factors, as discussed in detail below.

The results from the present study suggest that there is an association between the MTHFR C677T mutation and CL/P incidence while the correlation between A198C polymorphism and oral clefts is not supported. Several previous studies presented that the T allele of the MTHFR C677T polymorphism might be involved in the development of CL/Ps. Similar to our results, Wan et al found that the genetic polymorphism of MTHFR C677T is associated with the development of nonsyndromic cleft lip and palate in Chinese population \(^{25}\).

Also, a meta-analysis demonstrated that among Asians, CT heterozygote, TT homozygote and CT/TT of infants' MTHFR C677T variant could contribute to
