Abstract

**Background:** Type 4 pili (T4P) is an important virulence factor of Pseudomonas aeruginosa (P. aeruginosa). T4P pass the outer membrane through a large oligomeric channel made of a single PilQ protein that is most highly conserved at their C-termini. To develop a functional vaccine that can be used in clinical application, the secretin domain of the PilQ (PilQ<sub>380-706</sub>) was produced as a recombinant protein.

**Methods:** A 981 bp fragment of C-terminal of the pilQ secretin (pilQ<sub>1138-2118</sub>) from was designed into the prokaryotic expression vector pET28a. The presence of the pilQ<sub>1138-2118</sub> gene in the recombinant construct (pET28a/pilQ) was assessed by double digestion and PCR. After transformation, expression of the recombinant PilQ was induced by addition of IPTG. The expressed recombinant protein was purified by a modified method using a HisTrap affinity column and finally confirmed by SDS-PAGE. The functional activities of the produced PilQ<sub>380-706</sub> confirmed by Western blot analysis and twitching inhibition assay.

**Results:** The PCR and enzymatic digestion results showed the presence of the pilQ<sub>1138-2118</sub> gene in the construct. The protein electrophoresis showed that the molecular weight of the recombinant PilQ<sub>380-706</sub> is approximately 37 kDa. The Western blot analysis confirmed the specificity of specific IgG against the PilQ<sub>380-706</sub> protein. The PilQ<sub>380-706</sub> protein showed high biological activity in all of these standard assays.

**Conclusion:** Since, the PilQ<sub>380-706</sub> protein plays an important role in the biogenesis of pili; and thus, the primary establishment of P. aeruginosa; it seems that it can be used as a candidate vaccine or an adjuvant in the future studies.

**Keywords:** Pseudomonas aeruginosa, Proteins, Secretin

Introduction

*Pseudomonas aeruginosa* (P. aeruginosa) as an opportunistic human pathogen has a remarkable capacity to cause disease in susceptible hosts. It is the major colonizing microbial pathogen for Cystic Fibrosis (CF) patients<sup>1</sup> and a common infectious agent in nosocomial infections, such as patients with a severe burn, cancer, transplantation, AIDS, and other immunocompromising conditions. Despite improvements in antibiotic therapy, *P. aeruginosa* shows inherent and acquired resistance to many antimicrobial agents<sup>2</sup>. The pathogenesis of *P. aeruginosa* infections is multifactorial and is being affected by a complex of virulence factors; hence, it has made vaccine development difficult. Bacterial attachment is an initial and a critical step for the establishment of infection that involves bacterial adhesins and host receptors. One of the most important adhesins in *P. aeruginosa* is pil<sup>i</sup><sup>3</sup>.

Type IV pili (T4P) are the most common type of bacterial pilus and are thin, long, flexible, and retractable protein filaments. T4P are polarly localized, filamentous surface appendages present at the cell surface of a broad range of pathogenic and environmental bacterial species<sup>4</sup>. This adhesive cell surface structure is the prominent virulence factor that essential for initiation
of infection by mediating attachment to host cells, where non-piliated strains were reported to exhibit a 90% decrease in their ability to bind human alveolar cells, and also mutant strains that are unable to produce T4P are attenuated in virulence. Furthermore, another study revealed that piliated strains caused 28%-96% more cases of <i>P. aeruginosa</i> pneumonia as compared to non-piliated strains in a mouse model of infection. T4P play an important role in many processes including bacterial locomotion known as twitching motility, aggregation, infection by pilus-specific bacteriophage, DNA uptake, attachment to biotic and abiotic surfaces, host cell invasion and biofilm maturation. The pilus fiber is composed of hundred copies of PilA (or pilin, the major structural subunit) that are encoded by an operon that positively control by the <i>algR</i> regulator. The pilin monomer can be divided into three domains: a highly conserved hydrophobic N-terminal α-helix region; a hypervariable central region; and a semi-conserved C-terminal region containing β-strands. The C-terminal Receptor Binding Domain (RBD) of <i>P. aeruginosa</i> pilin is a suitable candidate for a peptide vaccine. The RBD contains a disulphide-bonded loop (DSL) that structurally is highly conserved among T4P of all species of <i>P. aeruginosa</i>, although the size of the DSL (from 12-31 amino acids) and its sequence is varied among pilin alleles.

The monoclonal antibody studies revealed that the C-terminal DSL of the pilin subunit mediates attachment to epithelium receptors, this finding suggests that PilA itself acts as both a major structural subunit and an adhesion. Finally, Type IV pilus has a common receptor among all strains of <i>P. aeruginosa</i>; however, the sequence diversity presents a considerable obstacle to the development of a protective RBD-based vaccine targeting the T4P.

Pili are rapidly extended and retracted via a most powerful molecular machine that organized with four subcomplexes: the cytoplasmic motor subcomplex (consisting of PilBTUCD), the inner membrane alignment subcomplex (PilMNOP), the outer membrane secretin pore subcomplex (PilQ and PilF), and the pilus itself (or PilA). There are significant structural and functional similarities between this pilus assembly apparatus and type II secretion system. T4P passes the outer membrane through a large oligomeric channel and makes a single protein. The PilQ (77 kDa; ORF PA5040) that encoded by the highly conserved pil<sup>-</sup>MNOPQ operon is a member of the so-called “secretin” family required for configuration of the outer membrane pore through which the pilus is extruded. The PilQ protein that is essential for T4P biogenesis consists of five conserved domains; Secretin N (380-449), Secretin (549-705), STN (306-354), HofQ (1-707) and AMIN (63-123). The secretin domains (Secretin N and Secretin) of the PilQ are more highly conserved at their C-termini. This region facilitates the passage of folded proteins, filamentous phage particles, DNA, and other macromolecules across the outer membrane. The secretin domain of PilQ (that’s mean PilQ<sub>380-706</sub>) was chosen as a new antigen and designed into expression vector pET28a.

In the present study, we designed a chimeric plasmid contains the pilQ<sub>1138-2118</sub> gene, which codes the immunologic domains of PilQ secretin (the C-terminal domain of the PilQ). To the best of our knowledge, for the first time, we report the purification and characterization of a novel recombinant PilQ (r-PilQ<sub>380-706</sub>) from <i>P. aeruginosa</i>. Furthermore, our data suggest that the protein has biological activities in both <i>in vivo</i> and <i>in vitro</i> conditions.

**Materials and Methods**

**Bacterial strains, plasmids, and media**

<i>Escherichia coli</i> (E. coli) strains Top10F and BL21(DE3) were used as preservation and expression hosts. The <i>P. aeruginosa</i> laboratory strain PAO1 (that kindly provided by Dr. Abdi from Department of Microbiology, Faculty of Biological Sciences, Alzahra University, Tehran, Iran) were performed. The recombinant plasmid pET28a/pilQ<sub>1138-2118</sub> Synthesized by Biomatik Corporation (Cambridge, Ont., Canada). All enzymes for DNA manipulations were obtained from NEB (USA), The Ni<sup>2+</sup>-NTA agarose was purchased from Qiagen (USA). The HRP-conjugated goat anti-rabbit IgG and Protein A/G agarose were obtained from ThermoFisher (formerly Invitrogen, USA). The strains were cultured in LB broth or on agar (HIMEDIA, India) at 37°C with or without 30 µg kanamycin/ml (Bioscience, Canada).

**Construction of the expression vector**

The pilQ<sub>1138-2118</sub> gene was inserted into the E. coli expression vector pET28a, in frame with a T7 promoter, kanamycin-resistant gene and the C and N-terminal six-His-tagged sequences. The gene containing BamHI and HindIII sites at the 5′ and 3′ ends, respectively. In the designation of the construct, we have inserted a start codon ATG immediately after the BamHI site (ggatccATG) of the pET28a vector, resulting in the correct framing of the gene of the insert. After transformation of the recombinant vector (pET28a/pilQ<sub>1138-2118</sub>) into E. coli Top10F competent cells, transformants were screened on LB plates supplemented with 30 µg kanamycin/ml. The recombinant vector was extracted from E. coli Top10F using plasmid extraction kit (Bio-Neer, Korea) according to manufacture instruction.

**Confirmation of the recombinant vector**

The pET28a/pilQ<sub>1138-2118</sub> vector was verified by polymerase chain reaction (PCR) and restriction enzyme digestion. The vector was treated with the restriction endonucleases BamHI and HindIII (Jena Bioscience Kit, Germany) according to manufacture instruction. The specific primers were designed for the pilQ<sub>1138-2118</sub> sequence of the <i>P. aeruginosa</i> PAO1 strain from NCBI (Gene ID: 880962). The gene was amplified from pET28a/pilQ<sub>1138-2118</sub> vector using the following specific...
36

Inclusion Bodies (IBs) were harvested by centrifugation the same buffer without EDTA and resuspended again centrifugation, the pellet was thoroughly washed with MgSO4 and DNase (0.01 M). To chelate the EDTA and remove DNA, 10 mM amycin at 22°C was added. The sonication was carried out on ice in lyse the cell wall and incubated for 30 minutes. To prevent denaturation, the solutions were optically and followed to incubate on ice for 20 min.

Expression and isolation of inclusion bodies
In order to overexpress the protein, the recombinant construct pET28a/pilQ1138-2118 was transformed into BL21 (DE3) and platted on LB agar containing kanamycin (30 µg/ml). To optimize the induction conditions, the colonies carrying the recombinant vector were grown in 5 ml of LB medium supplemented with kanamycin at 22°C. At OD600 nm of 0.8, expression of the r-PilQ380-706 was induced by addition of IPTG (BIO-SYNTH, Switzerland) to a final concentration of 1 mM. After 0, 1, 2, 3, 4 and 5 hr of induction, cells were harvested and the induced level of r-PilQ380-706 was determined by 12% SDS-PAGE electrophoresis.

For isolation of inclusion bodies, an overnight culture of E. coli BL21 (DE3) cells harboring pET28a/pilQ1138-2118 was diluted 100-fold in LB medium (1 liter) containing kanamycin and incubated at 22°C with shaking. When the OD600 of the culture reached 0.8, the promoter of the recombinant vector was induced by the addition of IPTG to the final concentration of 1 mM. After 4 hr, the induced cells were harvested by centrifugation at 8500×g for 10 min at 4°C and suspended in lysis buffer [20 mM sodium phosphate (pH=7.5), 10 mM EDTA, 1% (v/v) Triton X-100] to remove the contaminant proteins. Following freezing and thawing, the lysate was added to lyse the cell wall and incubated for 30 min in room temperature. The sonication was carried out on ice in the presence of PMSF (1 mM) as a protease inhibitor. To chelete the EDTA and remove DNA, 10 mM MgSO4 and DNase (0.01 mg/ml) was added, respectively and followed to incubate on ice for 20 min. After centrifugation, the pellet was thoroughly washed with the same buffer without EDTA and resuspended again in the buffer without EDTA and Triton-X100. The Inclusion Bodies (IBs) were harvested by centrifugation and stored at 4°C.

Solubilization, refolding and purification of r-PilQ380-706
The IBs were solubilized with Guanidinium Lysis Buffer [20 mM sodium phosphate, 500 mM NaCl, 6 M guanidine hydrochloride, pH=7.4]. The solubilized proteins were purified using Ni2+-NTA agarose (Qiagen, USA) according to the manufacturer’s instructions with modifications. Purifications were performed under denaturing and renaturing conditions (hybrid conditions). Briefly, after applying the sample to the column and washing with denaturing binding buffer [20 mM sodium phosphate, 500 mM NaCl, 8 M urea, pH=7.8], a linear gradient of urea from 7 M to 0 M of refolding buffer [20 mM sodium phosphate, 500 mM NaCl, 5% (v/v) glycerol, pH=6.0] was used at flow rate of 0.6 ml/min. The contaminant proteins were washed using native wash buffer [20 mM sodium phosphate, 500 mM NaCl, 20 mM imidazole, pH=8.0]. Finally, bound proteins were eluted in native elution buffer [20 mM sodium phosphate, 500 mM NaCl, 250-500 mM imidazole, pH=8.0]. The purified r-PilQ380-706 was dialyzed against phosphate buffered saline (PBS, pH=7.4) for imidazole removal and analyzed by 12% (w/v) SDS-PAGE followed by Coomassie brilliant blue G-250 staining. The protein concentration was quantitatively measured by using a NanoDrop 2000c spectrophotometer (Thermo Scientific, USA) and Bradford protein assay using standard albumin (Sigma, USA).

Preparation and purification of anti r-PilQ380-706 IgG
To determine the immunogenic nature of purified r-PilQ380-706, the female New Zealand white rabbits (Razi Vaccine and Serum Research Institute, Karaj, Iran) were immunized with 400 µg of the r-PilQ380-706 protein administered subcutaneously and boosted twice with 200 µg with 2 weeks intervals. The rabbits were anesthetized intramuscularly with an injection of a mixture of xylazine (10 mg/kg) and ketamine (50 mg/kg). The rabbits were bled prior to immunization and 2 weeks after the last immunization. Sera were collected from the retracted clot, clarified by centrifugation (2500×g) and then aliquoted and stored at -20°C. The rich fractions pooled and the specific IgGs (except IgG3) purified by using protein A/G agarose (Invitrogen, USA) according to the manufacturer's instructions and analyzed by SDS-PAGE. Protein concentration was quantitatively determined using NanoDrop (2000c spectrophotometer, Thermo Scientific, USA) and Bradford protein assay. Anti r-PilQ380-706 IgG and non-immune IgG were aliquoted at a concentration of 1-2 mg/ml and finally stored at -20°C until use.

SDS-PAGE electrophoresis and Immunoblot analysis
The bacterial pellets and purified protein were separated by SDS-PAGE. The samples were directly resuspended at a 2:1 ratio with 3× SDS-PAGE sample buffer in an appropriate volume of sample buffer. The discontinuous gel consisted of a 3% stacking gel and a 12% resolving gel which was run on a vertical electrophoresis unit (Mini PROTEAN 3 cell, Bio-Rad). To determine the functional activity, the purified r-PilQ380-706 protein was electrophoresed, and then transferred onto a PVDF membrane (Hi-bond Amersham Biosciences, USA) by a Bio-Rad apparatus at 25 V for over-
night. The membrane was blocked with 5% non-fat skim milk in TBST buffer (Tris buffer saline contain 0.1% Tween-20) for 2 hr at RT. After incubated with rabbit anti r-PilQ380-706 IgG (1:5000 diluted in blocking buffer) for 1 hr at RT, the membrane was incubated with HRP-conjugated goat anti-rabbit IgG for 1 hr at RT. The membrane was then washed 5 times with TBST for 5 min each. Finally, it was developed by adding 3, 3′-diaminobenzidine (DAB) solution (Sigma, USA) allowing it to incubate until bands were seen. The reaction was stopped by rising the membrane with water.

**Twitching inhibition assay**

To verify the functionality of the r-PilQ380-706 specific polyclonal IgG, the twitching inhibition assay was carried out by Castric et al. as follows. Different concentrations (0.1, 0.2 and 0.3 µg) of specific rabbit anti r-PilQ380-706 IgG (filter-sterilized) were added to LB broth (containing 1% (w/v) agar), which was poured into a 15×90 mm plastic Petri dish. After solidification, the plate was dried for 6 hr at room temperature. A single colony of the P. aeruginosa PA01 strain to be tested was stab-inoculated with a toothpick to the bottom of the plates. After omitting an 18 hr incubation at 37°C, the diameter zone of growth of different strains obtained at the interstitial surface of the agar and the plate was measured. For each assay, triplicate plates were examined.

**Statistical analysis**

The data were analyzed using one-way analysis of variance (ANOVA) and Student’s t-test (StatView). Statistical analysis was performed using the software GraphPad Prism version 6.0 for Windows, (GraphPad Software, San Diego, CA, USA). All data of this study are expressed as mean±SD. The p-values less than 0.05 was considered to be statistically significant.

**Results**

**Confirmation of the pET28a/pilQ1138-2118 construct**

The coding sequence of the secretin domain of pilQ (pilQ1138-2118) was constructed in the pET28a expression vector. Transformants were characterized by enzymatic digestion. The recombinant plasmid, pET28a/pilQ1138-2118, was extracted and its orientation confirmed by digestion with two restriction enzymes that mentioned above. The target fragments with the expected sizes are shown in figure 1. DNA gel electrophoresis of the PCR product resulted in single 981 bp band. Lane 2 and 3; BamHI/HindIII double digested the recombinant vector with BamHI and HindIII buffer, respectively. Two expected fragments from double digestion were observed on the gel (~5369 and 981 bp bands). Lane 4; the optimized PCR product of the pilQ1138-2118 gene (~961 bp band).

The recombinant plasmid, pET28a/pilQ1138-2118, was transformed into E. coli BL21 (DE3). The His-Tagged recombinant protein was purified from inclusion bodies by using Ni²⁺-affinity chromatography. Results from SDS-PAGE analysis of expression products showed that the PilQ380-706 protein expressed 4 hr after induction with IPTG. The expression product of the protein was approximately 37 kDa in molecular size (Figure 2). The purified protein was confirmed by western blotting as showed in figure 3. The yield of the purified PilQ380-706 protein was about 2.18 mg per liter of cul
Purification of a Novel and Functional Immunologic Domain of PilQ from *Pseudomonas aeruginosa*

Production of PilQ<sub>380-706</sub>-specific IgG and specificity analysis

Polyclonal antibodies against r-PilQ<sub>380-706</sub> were produced in rabbit and finally the specific IgG was purified by using protein A/G agarose (Invitrogen, USA) according to manufacturer's instruction. As shown in figure 4, β-Mercaptoethanol as a reducing agent break the hinge-region disulfide bonds and thus antibodies will dissociate into the heavy (51.4 kDa) and light (24.9 kDa) chains, respectively. To determine the specificity of the antiserum raised against purified r-PilQ<sub>380-706</sub>, western blot analysis was performed. The total cell extracts (induced and non-induced) and the purified PilQ<sub>380-706</sub> protein were immunoblotted and then hybridized with specific polyclonal IgG. Addition of HRP-conjugated goat anti-rabbit IgG showed that the PilQ<sub>380-706</sub> protein was substantially expressed by using the pET28a/pilQ<sub>1138-2118</sub> expression vector when IPTG was added at the early-exponential phase of growth and collecting the cells 4 hr after induction (Figure 3). Overall, our results indicated that the rabbit produced antibodies are highly specific to detect the r-PilQ<sub>380-706</sub>.

Twitching inhibition assay

Immunized and non-immunized rabbit sera were evaluated in the twitching inhibition assay for their biofunctional activity to inhibit the motility of PAO1 strain of *P. aeruginosa*. In this assay, NRS was used as control group. As shown in figure 5 and table 1, the r-PilQ<sub>380-706</sub> IgG was able to inhibit the motility of *P. aeruginosa* PAO1 so that the motility zone was significantly decreased compared to control group. In the presence of NRS, no immobilization was observed.

**Discussion**

Among the various recombinant immunodominant antigens identified as a candidate vaccine against *P. aeruginosa*, the outer membrane proteins have shown promising potential. Hence, we tried to improve the purification conditions to obtain the recombinant protein in the pET28a vector system. In the present study,
In recent years, high-throughput protein-refolding techniques have been developed for renaturation of inclusion bodies. These include three methods such as dilution, dialysis or solid-phase separation for renaturation of inclusion bodies. In the present study, for improvement of the refolding process, we have selected dilution and dialysis methods. In on-column purification, we used a decreased gradient of urea for the gradual removal of urea and renaturation of recombinant protein. This washing process followed by dialysis (with buffer exchange), in which there was no protein precipitation and aggregation. Our efforts at refolding of the solubilized proteins using dilution and dialysis methods were led to effectively refolded desired recombinant protein. We found that after chromatography by Ni-NTA agarose, unrelated proteins further decreased, this was lead to an increase in the refolding yield and purity. In the present study, we not only evaluated the efficiency of pET28a vector for the expression of the r-PilQ380-706 but also simultaneously developed a highly reproducible and efficient procedure for purification and scalable production of the recombinant protein with high purity. The procedure developed here may be useful in the efficient purification of other recombinant proteins highly expressed in E. coli as inclusion bodies. Generally, the protein (PilQ380-706) tends to be expressed as inclusion bodies at lower temperature, but the rate of expression is more slowly for correct folding. Now that culture under lower temperatures are beneficial to stabilization of structure and expression of soluble protein, and the increase of temperature did not significantly enhance PilQ380-706 expression (data not shown), the following induction was carried out at 22 °C. Overall, after several attempts to determine the optimal conditions, the highest amount of PilQ380-706 was produced by induction with 1 mM IPTG at 22 °C for 4 hr.

The immunoreactivity of purified r-PilQ380-706 under modified conditions was examined in vitro by twitching inhibition assay. The twitching inhibition assay results show that the antiserum raised against the r-PilQ380-706 can inhibit cell motility of P. aeruginosa PA01 in vitro. Immunoblot analysis demonstrated that the r-PilQ380-706-specific polyclonal IgG could detect the recombinant protein expressed in a prokaryotic cell (E. coli BL21). These findings indicate that the r-PilQ380-706 preserved correct folding. Since motility has been exhibited to be an important virulence factor in microbial pathogenesis, therefore, disruption of such a function by neutralizing and immobilizing antibodies in vivo may prove to be an advantageous prophylactic measure against pathogenic bacteria. These tests confirmed the bioactivity of the purified recombinant protein. Thus, the use of these reagents in the modified protocol does not have any adverse affects on the bioactivity of the protein. In the recent study, Koo et al showed that the absence of twitching motility of P. aeruginosa is correlated with the lack of PilQ multimer. We believe that, this is the first report on the expression and purification of the secretin domain of the PilQ380-706 protein with a His-tag in bacterial expression system. It is suggested that the r-PilQ380-706 could contribute as a vaccine or an adjuvant to control P. aeruginosa infection.
Conclusion

In conclusion, the present study described a modified method for expression, purification and refolding of r-PilQ380-706 from P. aeruginosa in E. coli. The recombinant protein was expressed in the form of inclusion bodies under the pET28a expression vector. Here, we developed a reproducible and simplified method to achieve significant yields of the protein. The purification of r-PilQ380-706 was done under the modified hybrid condition. The procedure developed in this study may be useful in the efficient purification of other recombinant proteins expressed in E. coli as inclusion bodies. This recombinant protein was biologically active and recommended to be used as a vaccine or an adjuvant.
