Abstract

\textbf{Background:} Brucellosis is still an important health problem in under developing countries and researches for finding efficient vaccine are going on. \textit{Brucella melitensis} (\textit{B. melitensis}) bp26 gene is a good candidate for brucellosis vaccine and investigations showed that \textit{Lactococcus lactis} (\textit{L. lactis}) with several positive characteristic are attractive for protein expression as a live delivery vectors. These fast growing bacteria need no aeration, are easy to handle, have no exotoxin, endotoxin and protease, so the cost of culturing is inexpensive.

\textbf{Methods:} \textit{B. melitensis} bp26 gene was cloned in food grade pNZ 8149 vector and expressed in \textit{L. lactis} NZ 3900.

\textbf{Results:} Results showed that we can produce a food-grade recombinant \textit{L. lactis} producing the \textit{B. melitensis} BP26 protein.

\textbf{Conclusion:} In this study, for Future evaluation about ability of \textit{L. lactis} as a live delivery vector, a food-grade recombinant \textit{L. lactis} producing the \textit{B. melitensis} BP26 protein was produced.

Introduction

Brucellosis is zoonotic diseases which made health and economic problem in many countries \textsuperscript{1}. In industrialized nations because of routine screening of domestic livestock and animal vaccination brucellosis in humans and livestock are relatively uncommon. Up to now no human vaccines are available, and current animal vaccines are both virulent in humans and lack clinical efficacy \textsuperscript{1}. Therefore, an efficient, economical and easily managed vaccine needs to be developed.

Researchers revealed that \textit{Brucella melitensis} (\textit{B. melitensis}) bp26 gene is a good immunogen and can be candidate for \textit{Brucella} spp vaccine \textsuperscript{3}. This gene encoding the 28 kDa periplasmic protein is named BP26, CP28 or Omp28 and is a target molecule to detect anti-\textit{Brucella} antibodies \textsuperscript{4,5}. To date, \textit{Lactococcus lactis} (\textit{L. lactis}) is attractive live delivery vector through mucosal routes for delivering bioactive proteins. \textit{L. lactis} enters through M cells and multiplied within phagocytic cells so releasing and spreading in deeper layer was occurred. Therefore induction of immune responses against \textit{L. lactis} antigens was Getting Started \textsuperscript{6-10}. PNZ8149 was used as the broad host range vector. This vector produces a cytoplasmic protein and to prevent protein removal by digestive enzymes or by other factors in the digestive tract, this protein was not designed to be secreted or attached to the cell surface of bacteria. Therefore, after entering of this recombinant bacterium through the M cells and up taking \textit{via} phagocytic cells, the probability of induction the immune system, through BP26 protein, is higher \textsuperscript{10}.

In this study for first time, \textit{B. melitensis} bp26 gene was cloned into the PNZ 8149 vector and expressed in \textit{L. lactis} NZ 3900 for used as a research experimental tool to find a good vaccine candidate.

Materials and Methods

\textbf{Bacterial strains and growth conditions}

Any bacterial strains and plasmids used in this study are showed in table 1. All \textit{L. lactis} strains were grown at 30°C on M17 media (Merck, Germany) containing 0.5% glucose (M17-glu) or lactose (M17-lac). All \textit{Escherichia coli} (E. coli) DH15a strain were grown at 37°C on Luria-Bertani (LB) medium (Merck, Germany) containing 50 μg/ml Ampicillin or 50 μg/ml kanamycin.

Amplification of bp26 gene

To amplify the bp26 gene, one pair of PCR primers was designed based on sequences published in Gene Bank (accession No. JF918758.1), and the restriction endonuclease sites of XbaI and SphI were added to both ends of the modified bp26 protein gene e based on the structure of PNZ8149 (forward: GCA CGATGAC ATG CAC CTG TCG TGC and reverse: TCT AGATTACTTGAT TTCAAAAAACGAC). Template DNA (pET28a+bp26) preserved by Our lab 3. The PCR was performed initial denaturation at 95°C for 2 min, followed by 34 cycles of 95°C for 1 min, 58°C for 1 min, and 72°C for 1 min. Extra polymerization in 72°C for 30 min. The PCR product consisting 753 bp was checked using agarose gel electrophoresis and then purified using a Fermentas Silica Bead DNA Gel Extraction Kit.

Cloning and transformation

The PCR product was cloned in to pTZ57R/T vector and transformed in E. coli DH5α competent cells. The recombinant pTZ57R/T plasmid was extracted and digested with two restriction enzymes (SphI /NEB Bio lab and XbaI/Fermentas Digestion Enzyme). At the same time the pNZ8149 plasmid was digested with both SphI and XbaI and purified. The purified desire was inserted into the pNZ8149. Competent L. lactis NZ39000 cells were then electro-transformed with the recombinant plasmids (Gene e-Pulsar; Bio-Rad, Hercules, CA, USA) and cultured on Elliker agar-lac bromo-cresol purple and incubated at 30°C for 48 hr. Transformants harboring the recombinant plasmids were verified through enzymatic digestion and PCR.

Expression of recombinant protein

Expression performed according to MoBiTec NICE_Expression_System and analyzed on 10% SDS-PAGE. To confirm the accuracy of the SDS-Page and protein expression, Western Blot was performed with Nitrocellulose Membrane (Sigma) and using the Trans-Blot SD cell (BIO-RAD). After blocking with TBST (tris-buffered saline, 0.05% Tween-20) buffer containing 5% skimmed milk at 4°C overnight, the membranes were incubated with a mouse IgG monoclonal antibody, anti-OMP28, (MyBioSource, Inc, USA) at a dilution 1:500 in phosphate-buffered saline (PBS) at a 37°C for 60 min. Then, the blots were washed and incubated with 1:2000 dilution of HRP-conjugated rabbit anti-

Results

PCR screening

Results showed that the expected DNA band of the bp26 gene had been amplified; the PCR product was approximately 753 bp in length plus the 12 bp restriction sites (Figure 1).

Digestion screening

Double-digestion confirms the size of bp26 gene (Figure 2).

Induced expression of the recombinant L. lactis

Results of bp26 gene expression on SDS-PAGE; as it is evident in the figure, with increasing Nisin (1 ng/ml) addition time, the amount of protein expression also increases. Protein production increase with Nisin and in 5th hr the high level of protein production was seen. Results indicated that the molecular weight of the expressed recombinant protein was approximately 28 kDa (Figure 3).

Western blot results showed that the produced protein was the B. melitensis omp28 (Figure 4). The result show that the binding of BP26 protein and its antibody occurred.
made to stimulate mucosal and cellular immunity. Today, investigations showed that using Lactic Acid Bacteria (LAB) as a live delivery vehicle for antigens can induce mucosal immunity and one of the most important candidates to produce mucosal vaccines. In this investigation, we used L. lactis 3900 as a gene delivery vehicle. Despite the fact that L. lactis is a non-commensal and non-colonizing bacterium at the level of the gastrointestinal tract, it can be easily taken up by M cells, and exhibits adjuvant/immune potentiating activity. As Brucella infections involve mainly bacterial entry through the mucosal routes, the development of successful approaches for oral vaccination could radically alter the current scene of brucellosis. Most published studies have evaluated the use of live vectors expressing Brucella antigens for vaccine delivery at the mucosal gut. At present, several recombinant proteins of Brucella have been evaluated as oral vaccine with L. lactis and sufficient evidence showed that they can induce protective immunity in mice. For example, in 2002, Luciana A. Ribeiro et al expressed Brucella abortus L7/L12 gene in L. lactis, under the nisin-inducible promoter. In another work, Daniela S. Pontes et al in 2003, revealed that a recombinant Lactococcus lactis strain producing L7/L12 under the control of nisin inducible promoter when orally administered to BALB/c mice, they could induced local humoral immune response and detected significant levels of anti-L7/L12 specific IgA in feces.

In 2012 DarwinSáez et al, transformed Brucella abortus (B. abortus) Cu-Zn Superoxide dismutase (SOD) in L. lactis revealed that orally vaccinated mice protected against challenge with the virulent B. abortus 2308 strain.

**Conclusion**

According to the investigations which mentioned above and considering that B. melitensis BP26 is a good immunogenic protein, in this study, we successfully constructed a food-grade recombinant L. lactis producing the B. melitensis BP26 protein for future researches about induction of immune response by this protein.
