Abstract

Background: Type 4 pili (T4P) is an important virulence factor of *Pseudomonas aeruginosa* (*P. aeruginosa*). T4P pass the outer membrane through a large oligomeric channel made of a single PilQ protein that is most highly conserved at their C-termini. To develop a functional vaccine that can be used in clinical application, the secretin domain of the PilQ (PilQ₃₈₀₋₇₀₆) was produced as a recombinant protein.

Methods: A 981 bp fragment of C-terminal of the *pilQ* secretin (*pilQ*₁₃₈₋₂₁₁₈) from was designed into the prokaryotic expression vector pET28a. The presence of the *pilQ*₁₃₈₋₂₁₁₈ gene in the recombinant construct (pET28a/*pilQ*) was assessed by double digestion and PCR. After transformation, expression of the recombinant PilQ was induced by addition of IPTG. The expressed recombinant protein was purified by a modified method using a HisTrap affinity column and finally confirmed by SDS-PAGE. The functional activities of the produced PilQ₃₈₀₋₇₀₆ confirmed by Western blot analysis and twitching inhibition assay.

Results: The PCR and enzymatic digestion results showed the presence of the *pilQ*₁₃₈₋₂₁₁₈ gene in the construct. The protein electrophoresis showed that the molecular weight of the recombinant PilQ₃₈₀₋₇₀₆ is approximately 37 kDa. The Western blot analysis confirmed the specificity of specific IgG against the PilQ₃₈₀₋₇₀₆ protein. The PilQ₃₈₀₋₇₀₆ protein showed high biological activity in all of these standard assays.

Conclusion: Since, the PilQ₃₈₀₋₇₀₆ protein plays an important role in the biogenesis of pili; and thus, the primary establishment of *P. aeruginosa*; it seems that it can be used as a candidate vaccine or an adjuvant in the future studies.

Introduction

Pseudomonas aeruginosa (*P. aeruginosa*) as an opportunistic human pathogen has a remarkable capacity to cause disease in susceptible hosts. It is the major colonizing microbial pathogen for Cystic Fibrosis (CF) patients¹ and a common infectious agent in nosocomial infections, such as patients with a severe burn, cancer, transplantation, AIDS, and other immunocompromising conditions. Despite improvements in antibiotic therapy, *P. aeruginosa* shows inherent and acquired resistance to many antimicrobial agents². The pathogenesis of *P. aeruginosa* infections is multifactorial and is being affected by a complex of virulence factors;

hence, it has made vaccine development difficult. Bacterial attachment is an initial and a critical step for the establishment of infection that involves bacterial adhesins and host receptors. One of the most important adhesins in *P. aeruginosa* is pili³.

Type IV pili (T4P) are the most common type of bacterial pili and are thin, long, flexible, and retractable protein filaments. T4P are polarly localized, filamentous surface appendages present at the cell surface of a broad range of pathogenic and environmental bacterial species⁴. This adhesive cell surface structure is the prominent virulence factor that essential for initiation

of infection by mediating attachment to host cells, where non-piliated strains were reported to exhibit a 90% decrease in their ability to bind human alveolar cells⁵, and also mutant strains that are unable to produce T4P are attenuated in virulence^{6,7}. Furthermore, another study revealed that pilated strains caused 28%-96% more cases of *P. aeruginosa* pneumonia as compared to non-piliated strains in a mouse model of infection⁸. T4P play an important role in many processes including bacterial locomotion known as twitching motility, aggregation, infection by pilus-specific bacteriophage, DNA uptake, attachment to biotic and abiotic surfaces, host cell invasion and biofilm maturation⁹. The pilus fiber is composed of hundred copies of PilA (or pilin, the major structural subunit) that are encoded by an operon that positively control by the *algR* regulator¹⁰. The pilin monomer can be divided into three domains: a highly conserved hydrophobic N-terminal α -helix region; a hypervariable central region; and a semi-conserved C-terminal region containing β -strands. The C-terminal Receptor Binding Domain (RBD) of *P. aeruginosa* pilin is a suitable candidate for a peptide vaccine¹¹. The RBD contains a disulphide-bonded loop (DSL) that structurally is highly conserved among T4P of all species of *P. aeruginosa*, although the size of the DSL (from 12-31 amino acids) and its sequence is varied among pilin alleles.

The monoclonal antibody studies revealed that the C-terminal DSL of the pilin subunit mediates attachment to epithelium receptors, this finding suggests that PilA itself acts as both a major structural subunit and an adhesion^{7,12}. Finally, Type IV pili has a common receptor among all strains of *P. aeruginosa*; however, the sequence diversity presents a considerable obstacle to the development of a protective RBD-based vaccine targeting the T4P¹¹.

Pili are rapidly extended and retracted *via* a most powerful molecular machine that organized with four subcomplexes: the cytoplasmic motor subcomplex (consisting of PilBTUCD), the inner membrane alignment subcomplex (PilMNOP), the outer membrane secretin pore subcomplex (PilQ and PilF), and the pilus itself (or PilA)¹³. There are significant structural and functional similarities between this pilus assembly apparatus and type II secretion system¹⁴. T4P passes the outer membrane through a large oligomeric channel and makes a single protein. The PilQ (77 kDa; ORF PA5040) that encoded by the highly conserved *pil-MNOPQ* operon¹⁵ is a member of the so-called "secretin" family required for configuration of the outer membrane pore through which the pilus is extruded⁹. The PilQ protein that is essential for T4P biogenesis consists of five conserved domains; Secretin_N (380-449), Secretin (549-705), STN (306-354), HofQ (1-707) and AMIN (63-123). The secretin domains (Secretin_N and Secretin) of the PilQ are more highly conserved at their C-termini. This region facilitates the passage of folded proteins, filamentous phage particles,

DNA, and other macromolecules across the outer membrane¹⁶. The secretin domain of PilQ (that's mean PilQ₃₈₀₋₇₀₆) was chosen as a new antigen and designed into expression vector pET28a.

In the present study, we designed a chimeric plasmid contains the *pilQ*₁₁₃₈₋₂₁₁₈ gene, which codes the immunologic domains of PilQ secretin (the C-terminal domain of the PilQ). To the best of our knowledge, for the first time, we report the purification and characterization of a novel recombinant PilQ (r-PilQ₃₈₀₋₇₀₆) from *P. aeruginosa*. Furthermore, our data suggest that the protein has biological activities in both *in vivo* and *in vitro* conditions.

Materials and Methods

Bacterial strains, plasmids, and media

Escherichia coli (*E. coli*) strains Top10F and BL21 (DE3) were used as preservation and expression hosts. The *P. aeruginosa* laboratory strain PAO1 (that kindly provided by Dr. Abdi from Department of Microbiology, Faculty of Biological Sciences, Alzahra University, Tehran, Iran) were performed. The recombinant plasmid pET28a/*pilQ*₁₁₃₈₋₂₁₁₈ synthesized by Biomatik Corporation (Cambridge, Ont., Canada). All enzymes for DNA manipulations were obtained from NEB (USA). The Ni²⁺-NTA agarose was purchased from Qiagen (USA). The HRP-conjugated goat anti-rabbit IgG and Protein A/G agarose were obtained from ThermoFisher (formerly Invitrogen, USA). The strains were cultured in LB broth or on agar (HIMEDIA, India) at 37°C with or without 30 μ g kanamycin/ml (Bioscience, Canada).

Construction of the expression vector

The *pilQ*₁₁₃₈₋₂₁₁₈ gene was inserted into the *E. coli* expression vector pET28a, in frame with a T7 promoter, kanamycin-resistant gene and the C and N-terminal six-His-tagged sequences. The gene containing BamHI and HindIII sites at the 5' and 3' ends, respectively. In the designation of the construct, we have inserted a start codon ATG immediately after the BamHI site (ggatccATG) of the pET28a vector, resulting in the correct framing of the gene of the insert. After transformation of the recombinant vector (pET28a/*pilQ*₁₁₃₈₋₂₁₁₈) into *E. coli* Top10F competent cells, transformants were screened on LB plates supplemented with 30 μ g kanamycin/ml. The recombinant vector was extracted from *E. coli* Top10F using plasmid extraction kit (Bio-ner, Korea) according to manufacture instruction.

Confirmation of the recombinant vector

The pET28a/*pilQ*₁₁₃₈₋₂₁₁₈ vector was verified by polymerase chain reaction (PCR) and restriction enzyme digestion. The vector was treated with the restriction endonucleases BamHI and HindIII (Jena Bioscience Kit, Germany) according to manufacture instruction. The specific primers were designed for the *pilQ*₁₁₃₈₋₂₁₁₈ sequence of the *P. aeruginosa* PAO1 strain from NCBI (Gene ID: 880962). The gene was amplified from pET28a/*pilQ*₁₁₃₈₋₂₁₁₈ vector using the following specific

primers: Forward: 5'-CCA GGT GAA CTA CGC CAA GG- 3' and Reverse: 5'-CGG TGT CAG GAA AAC CAG AAG T-3', which incorporated by *Bam*HI and *Hind*III restriction sites, respectively. Amplifications were performed in 25 μ l volumes containing 50 pM of each primers, 1X PCR master mix, and 25 ng of the vector. The PCR was performed in a master gradient thermocycler (Bio-Rad, USA). Template DNA was denatured at 94°C for 4 min prior to the start of PCR cycling, which consisted of denaturation at 94°C for 46 s, primer annealing at 61°C for 1 min, extension at 72°C for 1 min, repeating for 30 cycles followed by a final extension at 72°C for 10 min. The digested fragments and PCR product were separated by 1.2% (w/v) agarose gel electrophoresis.

Expression and isolation of inclusion bodies

In order to overexpress the protein, the recombinant construct pET28a/pilQ₁₁₃₈₋₂₁₁₈ was transformed into BL21 (DE3) and plated on LB agar containing kanamycin (30 μ g/ml). To optimize the induction conditions, the colonies carrying pET28a/pilQ₁₁₃₈₋₂₁₁₈ were grown in 5 ml of LB medium supplemented with kanamycin at 22°C. At OD₆₀₀ nm of 0.8, expression of the r-PilQ₃₈₀₋₇₀₆ was induced by addition of IPTG (BIOSYNTH, Switzerland) to a final concentration of 1 mM. After 0, 1, 2, 3, 4 and 5 hr of induction, cells were harvested and the induced level of r-PilQ₃₈₀₋₇₀₆ was determined by 12% SDS-PAGE electrophoresis.

For isolation of inclusion bodies, an overnight culture of *E. coli* BL21 (DE3) cells harboring pET28a/pilQ₁₁₃₈₋₂₁₁₈ was diluted 100-fold in LB medium (1 liter) containing kanamycin and incubated at 22°C with shaking. When the OD₆₀₀ of the culture reached 0.8, the promoter of the recombinant vector was induced by the addition of IPTG to the final concentration of 1 mM. After 4 hr, the induced cells were harvested by centrifugation at 8500 \times g for 10 min at 4°C and suspended in lysis buffer [20 mM sodium phosphate (pH=7.5), 10 mM EDTA, 1% (v/v) Triton X-100] to remove the contaminant proteins. Following freezing and thawing, the lysozyme (100 μ g/ml) was added to lyse the cell wall and incubated for 30 min in room temperature. The sonication was carried out on ice in the presence of PMSF (1 mM) as a protease inhibitor. To chelate the EDTA and remove DNA, 10 mM MgSO₄ and DNase (0.01 mg/ml) was added, respectively and followed to incubate on ice for 20 min. After centrifugation, the pellet was thoroughly washed with the same buffer without EDTA and resuspended again in the buffer without EDTA and Triton-X100. The Inclusion Bodies (IBs) were harvested by centrifugation and stored at 4°C.

Solubilization, refolding and purification of r-PilQ₃₈₀₋₇₀₆

The IBs were solubilized with Guanidinium Lysis Buffer [20 mM sodium phosphate, 500 mM NaCl, 6 M guanidine hydrochloride, pH=7.4]. The solubilized proteins were purified using Ni²⁺-NTA agarose (Qia-

gen, USA) according to the manufacturer's instructions with modifications. Purifications were performed under denaturing and renaturing conditions (hybrid conditions). Briefly, after applying the sample to the column and washing with denaturing binding buffer [20 mM sodium phosphate, 500 mM NaCl, 8 M urea, pH=7.8], a linear gradient of urea from 7 M to 0 M of refolding buffer [20 mM sodium phosphate, 500 mM NaCl, 5% (v/v) glycerol, pH=6.0] was used at flow rate of 0.6 ml/min. The contaminant proteins were washed using native wash buffer [20 mM sodium phosphate, 500 mM NaCl, 20 mM imidazole, pH=8.0]. Finally, bound proteins were eluted in native elution buffer [20 mM sodium phosphate, 500 mM NaCl, 250-500 mM imidazole, pH=8.0]. The purified r-PilQ₃₈₀₋₇₀₆ was dialyzed against phosphate buffered saline (PBS, pH=7.4) for imidazole removal and analyzed by 12% (w/v) SDS-PAGE followed by Coomassie brilliant blue G-250 staining. The protein concentration was quantitatively measured by using a NanoDrop 2000c spectrophotometer (Thermo Scientific, USA) and Bradford protein assay using standard albumin (Sigma, USA).

Preparation and purification of anti r-PilQ₃₈₀₋₇₀₆ IgG

To determine the immunogenic nature of purified r-PilQ₃₈₀₋₇₀₆, the female New Zealand white rabbits (Razi Vaccine and Serum Research Institute, Karaj, Iran) were immunized with 400 μ g of the r-PilQ₃₈₀₋₇₀₆ protein administered subcutaneously and boosted twice with 200 μ g with 2 weeks intervals. The rabbits were anesthetized intramuscularly with an injection of a mixture of xylazine (10 mg/kg) and ketamine (50 mg/kg). The rabbits were bled prior to immunization and 2 weeks after the last immunization. Sera were collected from the retracted clot, clarified by centrifugation (2500 \times g) and then aliquoted and stored at -20°C. The rich fractions pooled and the specific IgGs (except IgG3) purified by using protein A/G agarose (Invitrogen, USA) according to the manufacturer's instructions and analyzed by SDS-PAGE. Protein concentration was quantitatively determined using NanoDrop (2000c spectrophotometer, Thermo Scientific, USA) and Bradford protein assay. Anti r-PilQ₃₈₀₋₇₀₆ IgG and non-immune IgG were aliquoted at a concentration of 1-2 mg/ml and finally stored at -20°C until use.

SDS-PAGE electrophoresis and Immunoblot analysis

The bacterial pellets and purified protein were separated by SDS-PAGE. The samples were directly resuspended at a 2:1 ratio with 3 \times SDS-PAGE sample buffer. in an appropriate volume of sample buffer. The discontinuous gel consisted of a 5% stacking gel and a 12% resolving gel which was run on a vertical electrophoresis unit (Mini PROTEAN 3 cell, Bio-Rad). To determine the functional activity, the purified r-PilQ₃₈₀₋₇₀₆ protein was electrophoresed, and then transferred onto a PVDF membrane (Hi-bond Amersham Biosciences, USA) by a Bio-Rad apparatus at 25 V for over-

night. The membrane was blocked with 5% non-fat skim milk in TBST buffer (Tris buffer saline contain 0.1% Tween-20) for 2 hr at RT. After incubated with rabbit anti r-PilQ₃₈₀₋₇₀₆ IgG (1:5000 diluted in blocking buffer) for 1 hr at RT, the membrane was incubated with HRP-conjugated goat anti-rabbit IgG for 1 hr at RT. The membrane was then washed 5 times with TBST for 5 min each. Finally, it was developed by adding 3, 3'-diaminobenzidine (DAB) solution (Sigma, USA) allowing it to incubate until bands were seen. The reaction was stopped by rising the membrane with water.

Twitching inhibition assay

To verify the functionality of the r-PilQ₃₈₀₋₇₀₆-specific polyclonal IgG, the twitching inhibition assay was carried out by Castric *et al*¹⁷ as follows. Different concentrations (0.1, 0.2 and 0.3 µg) of specific rabbit anti r-PilQ₃₈₀₋₇₀₆ IgG (filter-sterilized) were added to LB broth (containing 1% (w/v) agar), which was poured into a 15×90 mm plastic Petri dish. After solidification, the plate was dried for 6 hr at room temperature. A single colony of the *P. aeruginosa* PAO1 strain to be tested was stab-inoculated with a toothpick to the bottom of the plates. After omitting an 18 hr incubation at 37 °C, the diameter zone of growth of different strains obtained at the interstitial surface of the agar and the plate was measured. For each assay, triplicate plates were examined.

Statistical analysis

The data were analyzed using one-way analysis of variance (ANOVA) and Student's *t*-test (StatView). Statistical analysis was performed using the software GraphPad Prism version 6.0 for Windows, (GraphPad Software, San Diego, CA, USA). All data of this study are expressed as mean±SD. The p-values less than 0.05 was considered to be statistically significant.

Results

Confirmation of the pET28a/pilQ₁₁₃₈₋₂₁₁₈ construct

The coding sequence of the secretin domain of *pilQ* (*pilQ*₁₁₃₈₋₂₁₁₈) was constructed in the pET28a expression vector. Transformants were characterized by enzymatic digestion. The recombinant plasmid, pET28a/*pilQ*₁₁₃₈₋₂₁₁₈, was extracted and its orientation confirmed by digestion with two restriction enzymes that mentioned above. The target fragments with the expected sizes are shown in figure 1. DNA gel electrophoresis of the PCR product resulted in single 981 bp band, which confirmed amplification of *pilQ*₁₁₃₈₋₂₁₁₈ gene (Figure 1). Sequence analysis of recombinant pET26b/*pilQ*₁₁₃₈₋₂₁₁₈ confirmed that there are no amplification errors and that construction was accurate.

Expression and purification of r-PilQ₃₈₀₋₇₀₆

To construct an expression system, the coding sequence of *PilQ*₃₈₀₋₇₀₆, whose theoretical molecular size is approximately 35 kDa, was constructed into expression vector pET28a to express a recombinant protein.

Figure 1. Agarose gel electrophoresis analysis of recombinant pET28a/*pilQ*₁₁₃₈₋₂₁₁₈ with restriction enzyme digestion. Lane M; DNA marker (1 kb), Lane 1; mono-digestion of the pET28a/*pilQ*₁₁₃₈₋₂₁₁₈ vector with BamHI. One expected fragment was observed on the gel (~6350 bp band). Lane 2 and 3; BamHI/HindIII double digested the recombinant vector with BamHI and HindIII buffer, respectively. Two expected fragments from double digestion were observed on the gel (~5369 and 981 bp bands). Lane 4; the optimized PCR product of the *pilQ*₁₁₃₈₋₂₁₁₈ gene (~961 bp band).

The recombinant plasmid, pET28a/*pilQ*₁₁₃₈₋₂₁₁₈, was transformed into *E. coli* BL21 (DE3). The His-Tagged recombinant protein was purified from inclusion bodies by using Ni²⁺-affinity chromatography. Results from SDS-PAGE analysis of expression products showed that the PilQ₃₈₀₋₇₀₆ protein expressed 4 hr after induction with IPTG. The expression product of the protein was approximately 37 kDa in molecular size (Figure 2). The purified protein was confirmed by western blotting as showed in figure 3. The yield of the purified PilQ₃₈₀₋₇₀₆ protein was about 2.18 mg per liter of cul-

Figure 2. SDS-PAGE analysis of the expression of r-PilQ₃₈₀₋₇₀₆ protein in *E. coli*. The total proteins of the BL21 harboring pET28a/*pilQ*₁₁₃₈₋₂₁₁₈ plasmid was harvested and loaded on 12% (v/v) SDS-PAGE after 4 hr induction with or without IPTG. (lane M) denote molecular weight marker proteins; (lanes 1) total cell lysate of non-induced bacteria; (lanes 2-7) 1-6 hr incubation after induction; (lane 8) purified r-PilQ₃₈₀₋₇₀₆ after HisTrap Chelating and Ni²⁺-affinity chromatography (~37 kDa).

After running the SDS-PAGE, the protein transferred onto PVDF membrane and detected with HRP-conjugated goat anti-rabbit IgG. (lane 1) total cell lysate of non-induced bacteria; (lane 2) total cell lysate of bacteria after 4 hr induction; (lane 3 and 4) purified r-PilQ₃₈₀₋₇₀₆ by Ni²⁺-affinity chromatography.

Figure 4. Coomassie blue-stained SDS-PAGE gel of affinity-purified antibodies. (lane M) molecular mass markers, in *kDa*; (lane 1) 10 *mM* glycine eluant; (lane 2) flowthrough from 100 *mM* glycine. Light chain (LC) and Heavy chain (HC) polypeptides were predicted to be 24.9 and 51.4 *kDa*, respectively.

ture media. In term of measured protein, no significant difference was observed between NanoDrop and Bradford protein assay.

Production of PilQ₃₈₀₋₇₀₆-specific IgG and specificity analysis

Polyclonal antibodies against r-PilQ₃₈₀₋₇₀₆ were produced in rabbit and finally the specific IgG was purified by using protein A/G agarose (Invitrogen, USA) according to manufacturer's instruction. As shown in figure 4, β-Mercaptoethanol as a reducing agent break

Figure 5. Twitching inhibition of *P. aeruginosa* PAO1 strain in the presence of r-PilQ₃₈₀₋₇₀₆ IgG on motility agar (LB broth with 1% w/v agar). The motility agar plates supplemented with either different concentrations of anti r-PilQ₃₈₀₋₇₀₆ IgG or non-immune rabbit serum (NRS) were stab inoculated with *P. aeruginosa* and incubated for 18 hr at 37°C. Different concentrations (0.3, 0.2 and 0.1 μg) of antiserum raised against r-PilQ₃₈₀₋₇₀₆ inhibited motility of *P. aeruginosa* PAO1 (b to d, respectively) compared with NRS (a).

the hinge-region disulfide bonds and thus antibodies will dissociate into the heavy (51.4 *kDa*) and light (24.9 *kDa*) chains, respectively. To determine the specificity of the antiserum raised against purified r-PilQ₃₈₀₋₇₀₆, western blot analysis was performed. The total cell extracts (induced and non-induced) and the purified PilQ₃₈₀₋₇₀₆ protein were immunoblotted and then hybridized with specific polyclonal IgG. Addition of HRP-conjugated goat anti-rabbit IgG showed that the PilQ₃₈₀₋₇₀₆ protein was substantially expressed by using the pET28a/pilQ₁₁₃₈₋₂₁₁₈ expression vector when IPTG was added at the early-exponential phase of growth and collecting the cells 4 hr after induction (Figure 3). Overall, our results indicated that the rabbit produced antibodies are highly specific to detect the r-PilQ₃₈₀₋₇₀₆.

Twitching inhibition assay

Immunized and non-immunized rabbit sera were evaluated in the twitching inhibition assay for their biofunctional activity to inhibit the motility of PAO1 strain of *P. aeruginosa*. In this assay, NRS was used as control group. As shown in figure 5 and table 1, the r-PilQ₃₈₀₋₇₀₆ IgG was able to inhibit the motility of the PAO1 strain, so that the motility zone was significantly decreased compared to control group. In the presence of NRS, no immobilization was observed.

Discussion

Among the various recombinant immunodominant antigens identified as a candidate vaccine against *P. aeruginosa*, the outer membrane proteins have shown promising potential. Hence, we tried to improve the purification conditions to obtain the recombinant protein in the pET28a vector system. In the present study,

the secretin domain of the PilQ gene (*pilQ*₁₁₃₈₋₂₁₁₈) from *P. aeruginosa* was designed into pET28a vector. This vector is one series of vectors without signaling regions allows accumulation of the PilQ₃₈₀₋₇₀₆ protein in inclusion bodies (insoluble form). These types of proteins have been efficiently de- and renatured. In addition, two 6×His-tag was designed at the N- and C-terminus of the r-PilQ₃₈₀₋₇₀₆ coding sequence. His-tag, a small purification partner, has been designed into pET28a vector to decrease the time and cost of protein purification procedures without affecting protein well folding and bioactivity. The pET system was chosen because it is a very powerful system developed specially for the cloning, expression and purification of recombinant proteins in *E. coli* and also has been utilized to overexpress exogenous proteins for decades. The PilQ₃₈₀₋₇₀₆ was expressed in BL21(DE3), carrying an inducible chromosomal gene for T7 RNA polymerase, which is controlled by an IPTG-inducible *lacUV5* promoter. pET-series vectors also contain a *lacI* gene that provides *lac* repressor molecules to downregulate both the *lacUV5*-controlled chromosomal T7 RNA polymerase and the *T7lac* promoter¹⁸. In the previous study, Fakhri *et al* cloned and expressed the conserved C-terminal fragment of the PilQ protein (PilQ₄₀₆₋₇₇₀) from *Neisseria meningitidis* into pET28a vector. They demonstrated that, when the recombinant vector transform into prokaryotic expression system, high level of protein is produced following nickel affinity chromatography¹⁹.

Most of the recombinant proteins thought aggregate as inclusion body, but can be solubilized and purified using hybrid condition. The significant increase in the yield of protein extraction from the inclusion bodies can be achieved by the addition of guanidine hydrochloride (G-HCl) as a solubilization agent. In this condition, the solubilized recombinant protein bind and wash under denature condition, and wash and elute under native conditions. Use of 6 M G- HCl alone as strong denaturant was sufficient for the solubilization of protein from inclusion bodies. In this study, we made the use of optimum concentration of non-ionic detergent (Triton X-100) that help to efficiently purify the r-PilQ₃₈₀₋₇₀₆ from inclusion bodies. The use of 1% Triton X-100 helps to improve the lysis conditions of cells for further solubilization of inclusion bodies. Furthermore, after three rounds of washes under native conditions, the proportions of unrelated proteins were considerably decreased (data not shown). In addition, 5% (v/v) glycerol was added in the refolding buffer as it enhanced the stability and efficiently elevating the yield of protein.

In recent years, high-throughput protein-refolding techniques have been developed for renaturation of inclusion bodies^{20,21}. These include three methods such as dilution, dialysis or solid-phase separation for renaturation of inclusion bodies²². In the present study, for improvement of the refolding process, we have

selected dilution and dialysis methods. In on-column purification, we used a decreased gradient of urea for the gradual removal of urea and renaturation of recombinant protein. This washing process followed by dialysis (with buffer exchange), in which there was no protein precipitation and aggregation. Our efforts at refolding of the solubilized proteins using dilution and dialysis methods were led to effectively refolded desired recombinant protein. We found that after chromatography by Ni-NTA agarose, unrelated proteins further decreased, this was lead to an increase in the refolding yield and purity. In the present study, we not only evaluated the efficiency of pET28a vector for the expression of the r-PilQ₃₈₀₋₇₀₆ but also simultaneously developed a highly reproducible and efficient procedure for purification and scalable production of the recombinant protein with high purity. The procedure developed here may be useful in the efficient purification of other recombinant proteins highly expressed in *E. coli* as inclusion bodies. Generally, the protein (PilQ₃₈₀₋₇₀₆) tends to be expressed as inclusion bodies at lower temperature, but the rate of expression is more slowly for correct folding. Now that culture under lower temperatures are beneficial to stabilization of structure and expression of soluble protein, and the increase of temperature did not significantly enhance PilQ₃₈₀₋₇₀₆ expression (data not shown), the following induction was carried out at 22 °C. Overall, after several attempts to determine the optimal conditions, the highest amount of PilQ₃₈₀₋₇₀₆ was produced by induction with 1 mM IPTG at 22 °C for 4 hr.

The immunoreactivity of purified r-PilQ₃₈₀₋₇₀₆ under modified conditions was examined *in vitro* by twitching inhibition assay. The twitching inhibition assay results show that the antiserum raised against the r-PilQ₃₈₀₋₇₀₆ can inhibit cell motility of *P. aeruginosa* PAO1 *in vitro*. Immunoblot analysis demonstrated that the r-PilQ₃₈₀₋₇₀₆-specific polyclonal IgG could detect the recombinant protein expressed in a prokaryotic cell (*E. coli* BL21). These findings indicate that the r-PilQ₃₈₀₋₇₀₆ preserved correct folding. Since motility has been exhibited to be an important virulence factor in microbial pathogenesis²³, therefore, disruption of such a function by neutralizing and immobilizing antibodies *in vivo* may prove to be an advantageous prophylactic measure against pathogenic bacteria. These tests confirmed the bioactivity of the purified recombinant protein. Thus, the use of these reagents in the modified protocol does not have any adverse affects on the bioactivity of the protein. In the recent study, Koo *et al* showed that the absence of twitching motility of *P. aeruginosa* is correlated with the lack of PilQ multimer²⁴. We believe that, this is the first report on the expression and purification of the secretin domain of the PilQ₃₈₀₋₇₀₆ protein with a His-tag in bacterial expression system. It is suggested that the r-PilQ₃₈₀₋₇₀₆ could contribute as a vaccine or an adjuvant to control *P. aeruginosa* infection.

Conclusion

In conclusion, the present study described a modified method for expression, purification and refolding of r-PilQ₃₈₀₋₇₀₆ from *P. aeruginosa* in *E. coli*. The recombinant protein was expressed in the form of inclusion bodies under the pET28a expression vector. Here, we developed a reproducible and simplified method to achieve significant yields of the protein. The purification of r-PilQ₃₈₀₋₇₀₆ was done under the modified hybrid condition. The procedure developed in this study may be useful in the efficient purification of other recombinant proteins expressed in *E. coli* as inclusion bodies. This recombinant protein was biologically active and recommended to be used as a vaccine or an adjuvant.
