Abstract

Background: Malignant melanoma is a highly aggressive malignant melanocytic neoplasm which resists against the most conventional therapies. Sea cucumber as one of marine organisms contains bioactive compounds such as polysaccharide, terpenoid and other metabolites which have anti-cancer, anti-tumor, anti-inflammatory and antioxidant properties. The present study was designed to investigate the anticancer potential of saponin extracted from sea cucumber Holothuria leucospilata alone and in combination with dacarbazine on B16F10 melanoma cell line.

Methods: The B16F10 cell line was treated with different concentrations of saponin (0, 4, 8, 12, 16, 20 μg/ml), dacarbazine (0, 1200, 1400, 1600, 1800, 2000 μg/ml) and co-administration of saponin-dacarbazine (1200 da+8 sp, 1200 da+4 sp) for 24 and 48 hr and the cytotoxic effect was examined by MTT, DAPI, acridine orange/propridium iodide, flow cytometry and caspase colorimetric assay.

Results: The results exhibited that sea cucumber saponin, dacarbazine, and co-administration of saponin-dacarbazine inhibited the proliferation of melanoma cells in a dose and time dependent manner with IC50 values of 10, 1400 and 4+1200 μg/ml, respectively. Morphological observation of DAPI and acridine orange/propridium iodide staining documented typical characteristics of apoptotic cell death. Flow cytometry assay indicated accumulation of IC50 treated cells in sub-G1 peak. Additionally, saponin extracted induced intrinsic apoptosis via up-regulation of caspase-3 and caspase-9.

Conclusion: These results revealed that the saponin extracted from sea cucumber as a natural anti-cancer compound may be a new treatment modality for metastatic melanoma and the application of sea cucumber saponin in combination with dacarbazine demonstrated the strongest anti-cancer activity as compared with the drug alone.

Keywords: Apoptosis, Dacarbazine, Melanoma, Saponins, Sea cucumbers

Introduction

Melanoma is the second most common cancer in the world which has been considered as a serious public health problem. This disorder is the most aggressive form of all skin cancers which have influenced the majority of human beings per year. Sun exposure, particularly UVB and UVA, was proposed as a potential inductive agent of melanoma malignancy. Nevertheless, although UV radiation is the leading cause of skin cancer, other causative agents consisting of viruses, mutagens, chemicals and genetic abnormality were considered important in complexity of this disorder.

Currently, due to high potential of metastasis in melanoma and low efficacy of conventional therapeutic methods, development of alternative methodologies with enhanced safety and efficacy to overcome this challenge is urgently needed. Drug resistance in melanoma mainly occurred through dysregulation of apoptosis, whereas drug transport, detoxification, and enhanced DNA repair may also exert a function. Therefore, the apoptosis induction deliberated the major target of anti-cancer chemotherapeutic strategies. Vin-cristine and vinblastine were proposed as popular natural based anti-tumor drugs which play an important role in cancer chemotherapy. Dacarbazine, temozolomide and cisplatin are used as common chemotherapeutic agents for melanoma treatment; although these modalities produce low response rates approximately less than 25%.
Dacarbazine is the first-line anti-cancer drug against melanoma which reveals anti-cancer effect via methylation of nucleic acids or direct DNA damage, however, resistance to conventional chemotherapy is considered the main obstacle to the treatment of this malignancy.

The studies exhibited that one of the approaches to alter the pharmacokinetic profile and toxicity related to this drug is combination therapy; however, it is well documented that naturally occurring compounds can be promising in cancer prevention due to low cost and minimum side effects. Hence, it is necessary to identify whether novel combination therapies are superior to single-agent dacarbazine.

High interest for discovering useful therapeutics from marine organisms has created novel opportunity to overcome cancer remedy challenge. It is reported that novel metabolites with potent pharmacological properties have been discovered from marine origin to fight cancer. Saponins are naturally occurring surface-active glycosides which are divided in two main groups of triterpenoid and steroids. These secondary metabolites are mainly derived from herbal extracts but also from some marine organisms which have been used widely in drug discovery due to their bio-medicinal characteristics.

The sea cucumbers are known as valuable sources of biologically active substances, which have gained interest among folk medicine researchers due to their use in the treatment of chronic inflammatory diseases. Therapeutic properties and potential health benefits of sea cucumbers can be attributed to the presence of an extensive array of bioactive compounds including chondroitin sulfates, sulfated polysaccharides, sterols, cerebrosides, peptides, triterpenoid glycosides (saponins), etc. These compounds are appealing because of their natural origin, long history of use as food, and lack of toxic effects. Recent studies have reported that sea cucumber saponin from various species can cause growth arrest against several types of cancerous cells including liver, lung, cervix, ovarian and melanoma.

The anti-neoplastic efficacy of natural saponins to trigger the apoptotic paradigm and scavenge free radicals constitutes a leading area of scientific oncological research; hence, cancer methodologies require the development of natural antitumor saponin compounds with minimum impact from side effects.

In the previous study, it was shown that sea cucumber saponin extracted from Holothuriz leucospilota (H. leucospilota) can exert toxicity on MCF-7 cancer cells and result in over expression of Bax and down regulation of Bcl-2 (as anti-apoptotic and as one of main pro-apoptotic factor of Bcl-2 family), leading to apoptosis administration in MCF-7 breast cancer cells.

Since scientific information on anti-melanoma effect of combination chemotherapeutics (Dacarbazine) and natural based bioactive compounds (extracted sea cucumber saponin) is still rather scarce, with this objective in mind, the present study was directed toward combination treatment of dacarbazine with sea cucumber saponin extracted from H. leucospilota to potentiate the cytotoxic effect of the drug in B16F10 melanoma cells.

**Materials and Methods**

**Chemicals**

B16F10 melanoma cell line was purchased from NCBI (National Cell Bank of Iran). RPMI-1640 medium, FBS (Fetal Bovine Serum), trypsin-EDTA and antibiotic (Penicillin-streptomycin) were purchased from Gibco (USA). MTT (3-[4, 5- dimethyl thiazol-2-yl]-2, 5-diphenyl tetrazolium bromide) and DAPI were obtained from Applichem (USA). Propodium Iodide (PI) and Acridine Orange (AO) were obtained from Sigma (USA). Caspase-3 and caspase-9 colorimetric assay kits were purchased from Abcam (England).

**Extraction and identification of crude saponin**

Crude saponin was isolated from the body wall of sea cucumber, Holothuriz leucospilota according to the method performed by Hu et al. Briefly, the ground sea cucumbers were extracted using methanol, dichloromethane and n-butanol, sequentially. The concentrated n-butanol fraction was loaded on diaion HP-20 and rinsed with dionized water, 80 and 100% ethanol. The 80% ethanol fraction was collected by evaporation as crude saponin and saponin identification was performed using TLC, erythrocyte lysis and FTIR which was reported previously.

**Cell culture and MTT assay**

For evaluation of cytotoxic effect of the sea cucumber saponin against melanoma cells, B16F10 cells were cultured in 96-well plate and treated with different concentrations of sea cucumber extracted saponin (0, 4, 8, 12, 16 μg/ml), dacarbazine (0, 1000, 1200, 1400, 1600, 1800, 2000 μg/ml) and synergistic treatment of saponin sea cucumber and dacarbazine (0, 1200 da+8 sp, 1200 da+4 sp μg/ml) for 24 and 48 hr. Then, cell viability was measured using 3-(4, 5-dimethylthiazol-2-yl)-2 and 5-diphenyltetrazolium bromide (MTT) assay. In this method, MTT and DMSO were added according to the company’s protocol, respectively. The absorbance of each well was measured at a wavelength of 560 nm by a spectrophotometer (Epoch, USA).

**Cell morphological assessment**

In order to investigate the effect of saponin sea cucumber, dacarbazine and synergistic treatment of saponin and dacarbazine in cell morphology, B16F10 cells were seeded in 24 well culture plates (10^5 cells/well) in RPMI supplemented with 10% FBS, after 24 hr adherence of cells. Treatment was performed at a different concentration. After 48 hr, the cells were examined under inverted microscope (Olympus, Japan).

**DAPI staining**

4’, 6-diamidino-2-phenylindole dihydrochloride
staining was used to examine the nuclear fragmentation. In this assay, the B16F10 cells were incubated with or without IC_{50} concentrations of sea cucumber saponin, dacarbazine and synergism treatment for 48 hr. Then, the cells were stained with DAPI and incubated for 10 min and the morphology of nuclei was observed under fluorescence microscopy (Olympus, Japan).

**AO/PI staining**

The morphological changes of apoptosis were evaluated by fluorescence microscopy. Briefly, the cultured cells were treated with IC_{50} concentration of saponin, dacarbazine and combination treatment for 48 hr. Then, the cells were rinsed with PBS. About 10 μl of the cell pellets were stained with a 10 μl fluorescent dye mixture containing equal volumes (100 μg/ml) of AO and PI. Finally, the cells were observed under a fluorescence microscope (Olympus, Japan).

**Detection of apoptosis**

To verify apoptosis in B16F10 treated cells, PI assay was performed. Exponentially growing cells were seeded and exposed with IC_{50} concentrations of saponin, dacarbazine and both of them for 48 hr. Then, they were centrifuged and mixed with 700 μl PI solution for 30 min in the darkness. Next, flow cytometric analysis was conducted using a FACScan laser flow cytometer (FACS Calibur, Becton Dickinson, USA).

**Caspase assay**

The enzymatic activities of caspase-3 and caspase-9 were measured using colorimetric caspase assay. The cells (1×10^6) were seeded in 6-well plate and exposed with inhibitory concentrations of saponin, dacarbazine and combination treatment. Treated cells were centri-fuged and incubated in 50 μl lysis buffer for 10 min on ice. After centrifugation, the supernatants were incubated with 20 μl caspase-3 and caspase-9 substrate at 37°C for 2 hr. Absorbance of the chromophore pNA separated from the caspase substrates was detected using Epoch spectrophotometer at 405 nm.

**Statistical analysis**

The statistical analysis was performed by SPSS, ANOVA software and p<0.05 was considered significant.

**Results**

**Cytotoxic assay**

To evaluate cytotoxicity of saponin, dacarbazine and synergistic treatment of saponin and dacarbazine on viability of B16F10 melanoma cells, MTT assay was examined. The results showed that saponin, dacarbazine and synergistic treatment had a marked dose-dependent effect on viability of B16F10 cells. The IC_{50} concentrations of saponin and dacarbazine were determined 10 and 1400 μg/ml (p<0.01), respectively. However, for a simultaneous treatment with both saponin and dacarbazine, low toxic concentration of 4 μg/ml saponin plus 1200 μg/ml dacarbazine for 48 hr caused an approximately 50% B16F10 cell death. Meanwhile the combination treatment of 8 μg/ml of saponin and 1200 μg/ml of dacarbazine and 10 μg/ml of saponin and 1000 μg/ml of dacarbazine reduced cell viability to 36.4, 28.7% in B16F10 cancer cells in 48 hr treatment (p<0.001). Consequently, treatment with sea cucumber saponin increased cytotoxicity of dacarbazine and caused more cytotoxicity in murine melanoma cells (Figure 1).

![Figure 1](image-url)

Figure 1. Dose dependent effects of sea cucumber saponin, dacarbazine alone and in combination on cell viability in B16F10 melanoma cells 24, 48 hr. As shown, in combination treatment, IC_{50} value obtained in low toxic concentration of each treatment alone demonstrating potent activity of combination therapy on melanoma cell viability (sp=saponin, dr=dacarbazine).

*p<0.05, **p<0.01 and ***p<0.001 were considered significant between control and experimental groups.
Monitoring of cell morphology

The morphology of untreated and treated melanoma cells has been shown in figure 2A. The apoptosis morphological changes include cell rounding, reducing cell volume, cytoplasmic blebbing, plasma membrane distortion as well as nuclear condensation and apoptotic bodies. The morphological observation indicated that IC_{50} concentration of saponin, dacarbazine and mixture of saponin and drug conducted apoptosis changes in morphology of melanoma cells including cell shrinkage, reducing cell volume and irregularities in cell contour and size which are all well known as the apoptotic characteristics (Figure 2A).

Detection of apoptosis by DAPI staining

DAPI staining as fluorescence DNA binding agent was used for evaluating nuclear apoptosis detection. Based on morphological observation from DAPI staining, DNA fragmentation occurred in IC_{50} concentration of saponin as well as IC_{50} concentration of dacarbazine and combination treatment (Figure 2B).

Monitoring morphological characterization of apoptosis by AO/PI staining

Apoptosis is the crucial cell death mechanism induced in response to cytotoxicity of chemotherapeutic drugs in cancer cells. AO/PI method is used to monitor apoptotic, necrotic and alive cells by their color (green,
Sea Cucumber Saponin and Dacarbazine

In apoptotic cells, appearance of a sub-G1 peak is believed to be the result of endonuclease activation which is not observed in necrotic cells. Figure 3 shows that IC_{50} concentration of saponin, dacarbazine and synergistic treatment increase the sub-G1 peak (apoptotic peak). These results supported this idea that apoptotic cell death is involved in cytotoxicity of saponin, dacarbazine and combination treatment in B16F10 cells (Figure 3).

**Activation of caspase-9 and caspase-3 in B16F10 cells**

The caspase-cascade has an essential role in apoptosis which is divided as apoptosis activator (caspase-9) and apoptosis executioner (caspase-3). As exhibited in figure 4, caspase-3 and caspase-9 activation was significantly enhanced in a dose dependent manner with IC_{50} value of saponin, dacarbazine and synergistic treatment compared with the untreated cancer cells. Moreover, in comparison to treatment groups, the caspase activity was markedly increased in combination treatment groups treated with 4 \( \mu \text{g/ml} \) saponin, 1200 \( \mu \text{g/ml} \) dacarbazine and 8 \( \mu \text{g/ml} \) saponin/ 1200 \( \mu \text{g/ml} \) dacarbazine compared to 1400 \( \mu \text{g/ml} \) dacarbazine alone indicating that synergistic treatment with sea cucumber saponin and dacarbazine induced more potent caspase activation in B16F10 cells as compared with drug treatment. Thus, these results elucidated the involvement of intrinsic pathway in cytotoxicity of saponin, dacarbazine and combination treatment in melanoma cells.

**Discussion**

Malignant melanoma arises from unregulated cell growth which is the leading cause of morbidity in the world. In spite of multiple conventional chemotherapeutic strategies for melanoma treatment, this condition remains as one of main oncological research fields. Dacarbazine is a standard antineoplastic drug commonly used for treating melanoma, though this drug may induce side effects, because it restricts normal cell proliferation.

In the present study, it was aimed to evaluate the cytotoxicity of sea cucumber saponin, focusing on reduction of the cytotoxic effect of dacarbazine on melanoma cancer cells. As shown in this study, treatment of B16F10 cells with sea cucumber saponin and dacarbazine presented a dose-dependent inhibitory effect on melanoma cell viability. In addition, the findings from fluorescence microscopy and flow cytometry confirmed that the cytotoxicity of sea cucumber saponin and dacarbazine alone and in combination was related to apoptosis and dacarbazine along with sea cucumber saponin elicited intrinsic apoptosis pathway which was verified through caspase-3 and -9 activation.

Chemotherapeutic modality using cisplatin, dacarbazine, temozolomide, doxorubicin and 5-FU which are used extensively as chemotherapeutic agents in numerous cancer therapies, have not completely prevented recurrence and metastasis of tumors. One of the main problems with dacarbazine is associated with its cytotoxicity in normal cell growth. Meanwhile, dacarbazine renders the activation of the extracellular signal-regulated kinase pathway and up-

![Figure 4. Effect of sea cucumber extracted saponin and dacarbazine on caspase-3 and caspase-9 activity. As shown, incubation of B16-F10 cells with increasing concentration of sea cucumber saponin and dacarbazine were enhanced significantly 48 hr after treatment, in addition more caspase activation resulted in combination treatment groups. *p<0.01, **p<0.001 were considered significant between experimental groups and control.](image-url)
regulation of IL-8 and VEGF secretion renders melano-
oma cells which are considered as a possible escape
mechanism in chemotherapy and results in resistance
against the cytotoxic effects of the drug. These side
effects might conduct the cells to more aggressive phe-
notype, and metastatic capabilities.

A major limitation of cancer chemotherapy is the
inability to escalate doses of an anticancer drug due to
intolerable cytotoxic side effects. This limitation can be
overcome by using a combination of natural based
drugs administered at lower dosage. The most widely
used chemotherapeutic combination therapy includes
application of cisplatin, vinblastine and dacarbazine. Doxorubicin (DOX) is a type of chemotherapeutic
agent which is commonly used to treat a wide range of
cancers. Nevertheless, DOX induced severe toxicity
and undesirable side effects. Oktem et al designed a
study to determine the combination of resveratrol as a
potential antioxidant and DOX to reduce the toxic
effects of cellular damage caused by doxorubicin.

Aloe-emodin (AE) is a natural hydroxyanthraquinone
compound of Aloe vera L. which has been known as an effective anticancer agent in traditional medicines. Tabolacci et al designed a study to investigate the antineoplastic effect of AE on B16–F10 melanoma cells and their results showed the anti-proliferative and anti-metastatic properties of Aloe-emodin against mouse metastatic melanoma cells.

In 2013, Zhang et al showed that Trametes robini-
phila Murrill (Huaier) aqueous extract can be used as a
promising complementary agent against melanoma
cancer. Huaier has been well-known in Traditional
Chinese Medicine (TCM) as an anti-cancer agent
which exerted cytotoxic effect against melanoma via
inhibition of cell proliferation and induction of apop-
tosis through the mitochondrial pathway. Green tea is
an evergreen plant that possesses antioxidant and pro-
oxidant activities, so that it is recognized as a cancer
preventive agent. In 2012, Fujiaki et al evaluated the
synergistic effect of chemotherapeutic drugs with green
tea catechin and approved synergistic treatment with
this natural extract and indicated that anti-cancer drugs
induced apoptotic cell death, prevented tumor for-
mation and proliferation.

Marine-derived natural products such as saponins
represent therapeutic properties to eradicate cancer.
Accordingly, recent studies have gained an increasing
attention towards finding and producing novel natural
drugs from marine organism as a potential source of
anticancer drugs. In case of improving the effective-
ness of chemotherapeutic strategies, reducing the dos-
age of anticancer drugs is considered appreciable in
minimizing adverse side effects.

Jasmine B is a natural product which is isolated from
the marine sponges Pachastrissa sp. and Jaspis sp.
Salma et al reported that Jasmine B acts as apoptosis
inducer and its cytotoxic effect is produced via cas-
pase-dependent pathway against murine and human
melanoma cells.

In previous research, a study was designed to isolate
and evaluate the cytotoxic effect of Persian Gulf brittle
star (Ophiocoma erinaceus) saponin and revealed that
the extracted saponin exerted hemolytic and cytotoxic
effect on cervical carcinoma cells. Furthermore, the
anti-proliferative properties and effects of brittle star
dichloromethane extract on B16F10 melanoma cells
were evaluated and it was indicated that marine echi-
noderm extracts can exert their cytotoxicity on melano-
ma cells via apoptosis recruitment. Li et al examined
the sea cucumber Holothuria nobilis Selenka saponin, echinoside A, as a significant anticancer agent
in prostate carcinoma cells and their results showed that
echinoside A could inhibit Topoisomerase2 (Top2)
and decrease the tumor growth suggesting anti-cancer
potential of marine saponins in cancer therapies. In
another study, it was demonstrated that saponin ex-
tracted from sea cucumber (H. leucospilota) has potent
hemolytic and cytotoxic effect against lung cancer cells
so these compounds may present a great opportunity to
be used as effective anti-cancer agents.

Consequently, combination therapies based on natu-
ral products and approved drugs, such as the combina-
tion of sea cucumber saponin and dacarbazine can be
proposed as novel chemotherapeutic modality against
melanoma. Furthermore, future studies are required
about the detailed mechanisms involved in apoptosis
pathway induced by sea cucumber saponin and dacar-
bazine.

Conclusion

Our results clearly indicated that sea cucumber
saponin and dacarbazine exerted cytotoxicity on melano-
ma cells through apoptosis recruitment and admin-
istration of saponin extracted from sea cucumber in-
creases the sensitivity of melanoma cells to chemother-
paeutic drug, exhibits the strongest anti-cancer effect
compared with dacarbazine and may provide a promis-
ing new therapeutic approach to melanoma. In addi-
tion, dacarbazine in combination treatment with sea
cucumber saponin render anti-cancer properties via
intrinsic apoptotic pathway which was confirmed by
activation of caspase -3,-9. These outcomes represent
reliable evidence supporting the application of sea cu-
umber saponin as an adjunct to dacarbazine in adv-
ancement of effective therapy in melanoma.
